19 ABSTRACT (Continue on reverse if necessary and identify by block number) From 26 May 1990 through 9 June 1990 the NADC/ERIM P-3/SAR collected calibration data over Andros Island. Several calibration reflectors were deployed on the ground at Andros town. The P-3/SAR typically imaged the reflectors during one pass at the start of each day's flight and one pass at the end of the day. These images were quickly processed to verify focussing and linearity of the SAR. The calibration activity demonstrated that the P-3/SAR was operating properly during the mission and that the data is calibratable.

1.0 INTRODUCTION

From 26 May 1990 through 9 June 1990 the NADC/ERIM P-3/SAR collected calibration data over Andros Island. Several calibration reflectors were deployed on the ground at Andros town. The P-3/SAR typically imaged the reflectors during one pass at the start of each day's flight and one pass at the end of the day. These images were quickly processed to verify focussing and linearity of the SAR. The calibration activity demonstrated that the P-3/SAR was operating properly during the mission and that the data is calibratable.

2.0 GROUND TRUTH FOR CALIBRATION ARRAY AT ANDROS ISLAND

A map of Andros town is given in Figure 1. The reflectors were deployed in the water catch area indicated on the figure. Trihedrals were deployed in two configurations: (1) a radiometric array to be observed in stripmap mode and (2) two large reflectors to be observed in spotlight L-band mode.

The radiometric array consisted of triangular trihedral reflectors ranging in size from 45 cm to 90 cm on a side; a map of this array is shown in Figure 2. The reflectors were set on the smooth concrete slabs (level to within 1 degree) which comprised the water catch area. They were then oriented to a precision of ± 0.5 degree for a radar look direction of 270° T. A picture of the water catch area with the trihedrals deployed is presented in Figure 3.

In Figure 4 a map of the spotlight mode reflector array is shown. This array consisted of two large triangular trihedrals (42" long edges) which were deployed for a radar look direction of 10° T. They did not interfere with the radiometric array because when viewed from the backside the trihedrals have a very low radar cross section (RCS).

3.0 CALIBRATION ANALYSIS

The calibration analysis consisted at two main studies: (1) a detailed image quality and linearity study for one pass and (2) a daily system calibration pass analyses.

3.1 DETAILED IMAGE QUALITY AND LINEARITY STUDY: JUNE 3, 1990

A detailed image quality and system linearity study was done for June 3, 1990 pass #36. In Figures 5, 6, 7, and 8 the X-VV, L-VV, C-VV, and L-HH channel images of the radiometric calibration array at Andros town and some surrounding areas are presented.

The images all appear to be focused and to verify this an impulse response (IPR) analysis of the trihedrals in the radiometric array was performed for each image. In Figure 9, the IPR listing is given for the X-VV channel. In Figures 10, 11, 12, and 13 azimuth and range cuts of the IPR are plotted for the largest and smallest reflectors. This analysis was repeated for the L-VV, C-VV and L-HH imagery and the results are presented in Figures 14 through 28. The image quality was good for all the images and the resolution (as defined by 3 dB widths) was approximately 2m in range and 3m in azimuth. The X- and C-band focused slightly better than L-band.

A system linearity study was also performed for all the images from pass #36 on June 3, 1990. The linearity of the radar system can be examined by comparing the normalized intensity of a reflector to the expected RCS of the reflector. The normalized intensity is the intensity of the reflector integrated over the region of the response greater than one-half the peak intensity and then corrected for the antenna pattern, range falloff, background clutter level, transmitted power, and system attenuator setting. When the normalized intensity of several reflectors in the image is plotted versus the theoretical RCS of the reflectors a linear relationship should be observed. A non-linear relationship would indicate that the system is saturating, the receiver

is non-linear, or the signal is in the noise floor of the system. In Figure 29 a plot of the reflectors theoretical RCS vs. normalized intensity is presented. This plot illustrates that the SAR is operating properly. In Figure 30 a computed list is presented with the reflector data and the results of a least-square linear fit. This fit indicates a slope of 1.019 (close to the ideal of one) and a mean square error from the fitted line of 0.34 dB. This analysis was repeated for L-VV, C-VV, and L-HH and the results are presented in Figure 31 through 36. The system was operating linearly for all the data examined.

3.2 DAILY SYSTEM CALIBRATION PASSES

In Tables 1 through 10 each pass over the calibration array at Andros Island is examined. Typically the impulse response listing for a large and small reflector from each channel is presented. This provides a quick check of focusing and linearity on a daily basis. It appears the system operated properly during the mission. From these tables the focusing of the system can be verified by examining the 3 dB widths of the IPR. The linearity of the system can be verified by comparing the relative 3 dB energy of the reflectors to the theoretical RCS of the reflectors and showing the two are linearly proportional.

4.0 CONCLUSION

The image quality and linearity measures indicated the P-3 system operated properly during the mission from 26 May 1990 through 9 June 1990.
